Inst : Jagiellonian University, Krakow, Poland

Title : Intensity Ratio in the "Forbidden" Doublet λ 2958 and λ 2927 A. U. in the Spectrum of Atomic Oxygen

Orig Pub : Acta phys. polon., 1958, 17, No 5, 345-351

Abstract : A study was made of the intensity ratio of the lines of the forbidden doublet OI, corresponding to the transitions $1s_0 \rightarrow 3p_1$ ($\lambda = 2972.2 \text{ \AA}$) and $1s_0 \rightarrow 3p_2$ ($\lambda = 2958.1 \text{ \AA}$). The former line, previously discovered, corresponds to magnetic dipole radiation, while the second line, first observed in this investigation, corresponds to electric quadrupole radiation. A special U-shaped tube was developed for the observation of this

line, with electrodes made of pure aluminum foil, having large surface (120 cm^2). The horizontal portion of the tube, the end of which was used for the observation, was 45 cm long and 0.6 cm internal diameter. The optimum conditions for the observation of the forbidden line were: pressure of He -- 3 to 4 mm mercury, of pure oxygen -- 0.3 to 0.5 mm mercury, current density in the working portion of the tube -- 0.5 amp/cm^2 , voltage 600 volts, power 1.5 kw. The foregoing exact values of the wave lengths of these lines were determined by microphotometry of the spectra, obtained with the aid of a quartz spectrograph of large aperture (1:5). The exposure time was three hours. The dispersion curve in this region of the spectrum was determined from the following lines: Hg 2967.5 and 2975.2 $\text{\AA}$, He 2945.1 $\text{\AA}$, and in the second positive series of the nitrogen band 2953.2, 2962.0 and 2976.8 $\text{\AA}$. By means of a stepped Rh attenuator with

LOGICAL SYMPTOMS - Leczenie gruźlicy kręgosłupa powiklanej objawami
neurologicznymi - Llaska O. and Marek A. Klin. Neurochir. A.M.,
Kraków - NEUROL. NEUROCHIR. PSYCHIAT. POL. 1958, 8/1 (85-92) Tables 2
Of 17 operated patients, in 8 the diagnosis of tb of the spinal cord was established
before the intervention, in 8 the diagnosis was made during the operation and the
last patient had a pathologically broken vertebra. It is postulated that in case of
Pott's disease an operation is indispensable. Conservative treatment is possible
in cases of insignificant paraparesis but only when under strict control.

801. LISZKAI L. Sect. of Pathol. László munic. Hosp., Budapest. *Myocarditis in fatal poliomyelitis ACTA MORPH. ACAD. SCIENT. HUNG. (Budapest) 1955, 5/3-4 (385-392) Tables 1 Illus. 5

The author refers to the literature on cardiac involvement complicating poliomyelitis and reports on the autopsy findings in 27 cases during 1950-53, noting particularly the lesions in the CNS which might be partially accountable for trophic myocardial changes. Gross examination of the heart was without distinct characteristics. Myocardial lesions were commonest in the left ventricle and the predominant lesion was an infiltration of the interstitial connective tissue, often around the blood vessels, with pericapillary haemorrhages and frequent small areas of myofibrillary fragmentation. The more severe cases (29.6%) showed acute muscular destruction; the majority, however, showed inflammatory infiltration without muscular damage. The pericardium was involved in 13 cases, and the nerve plexuses in them had lost structural identity. In all cases the CNS was involved, and some of the cases showed poliomyelitic lesions in one or more of the following structures, which may have something to do with producing cardiac changes, but this will require additional evidence to support the neurogenic viewpoint: pericardial nerves, vagal plexus, nodose ganglion, or the superior cervical ganglion. However, that acute poliomyelitis causes myocardial involvement appears certain.
